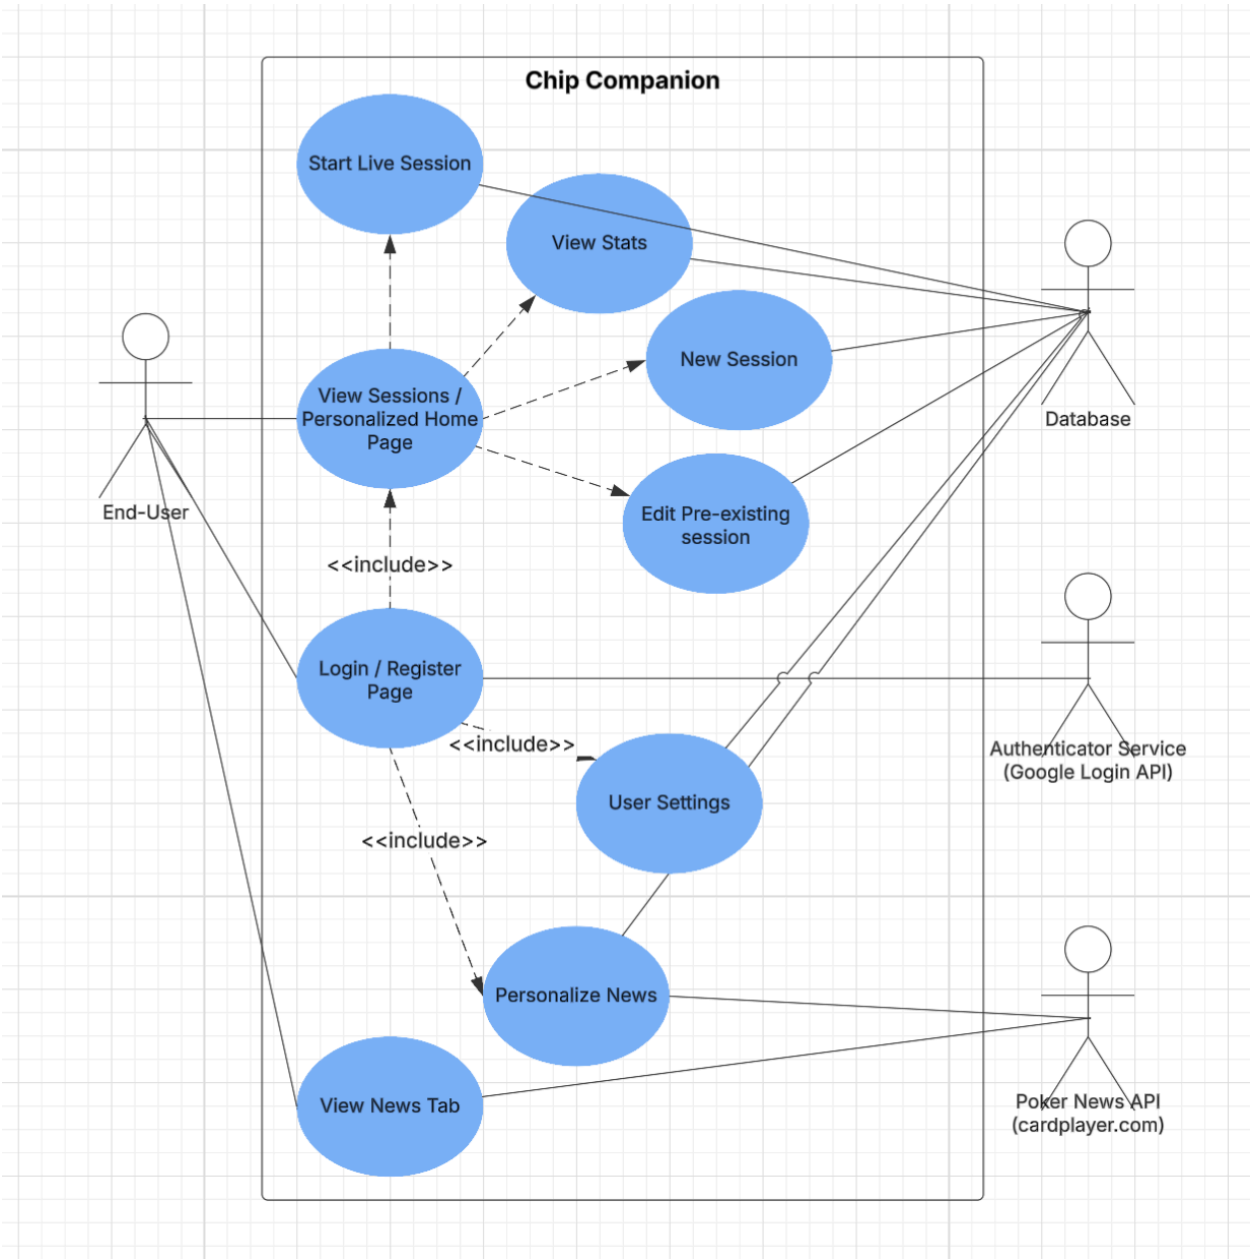
4. Application Name: Chip Companion
5. Application Description:
    a. Chip Companion is a poker bankroll tracker designed for serious players who want to monitor and improve their performance over time. Users can log and upload detailed session data, including buy-in, cash-out, rebuys, time played, location, and stakes. The app also supports live session tracking, allowing players to update their progress in real time with chip counts, rebuys, tips, and other relevant details. By centralizing this information, the application helps users maintain an accurate and organized record of their poker activity.

    In addition to tracking, the application provides meaningful analytics to help users better understand their results. These features include performance trends over time, insights into which days or game types are most profitable, and advanced calculations such as expected value and variance based on a player's win rate. All user data is securely stored in hosted databases accessed through the app's API, ensuring reliability and accessibility across sessions. Users will have the option to update their profile settings such as changing their username or password or updating their preferred currency. Additionally, users will have the option to sign in with their Google account. If time allows, the application may also feature a news section to keep users updated on the latest developments in the poker world.

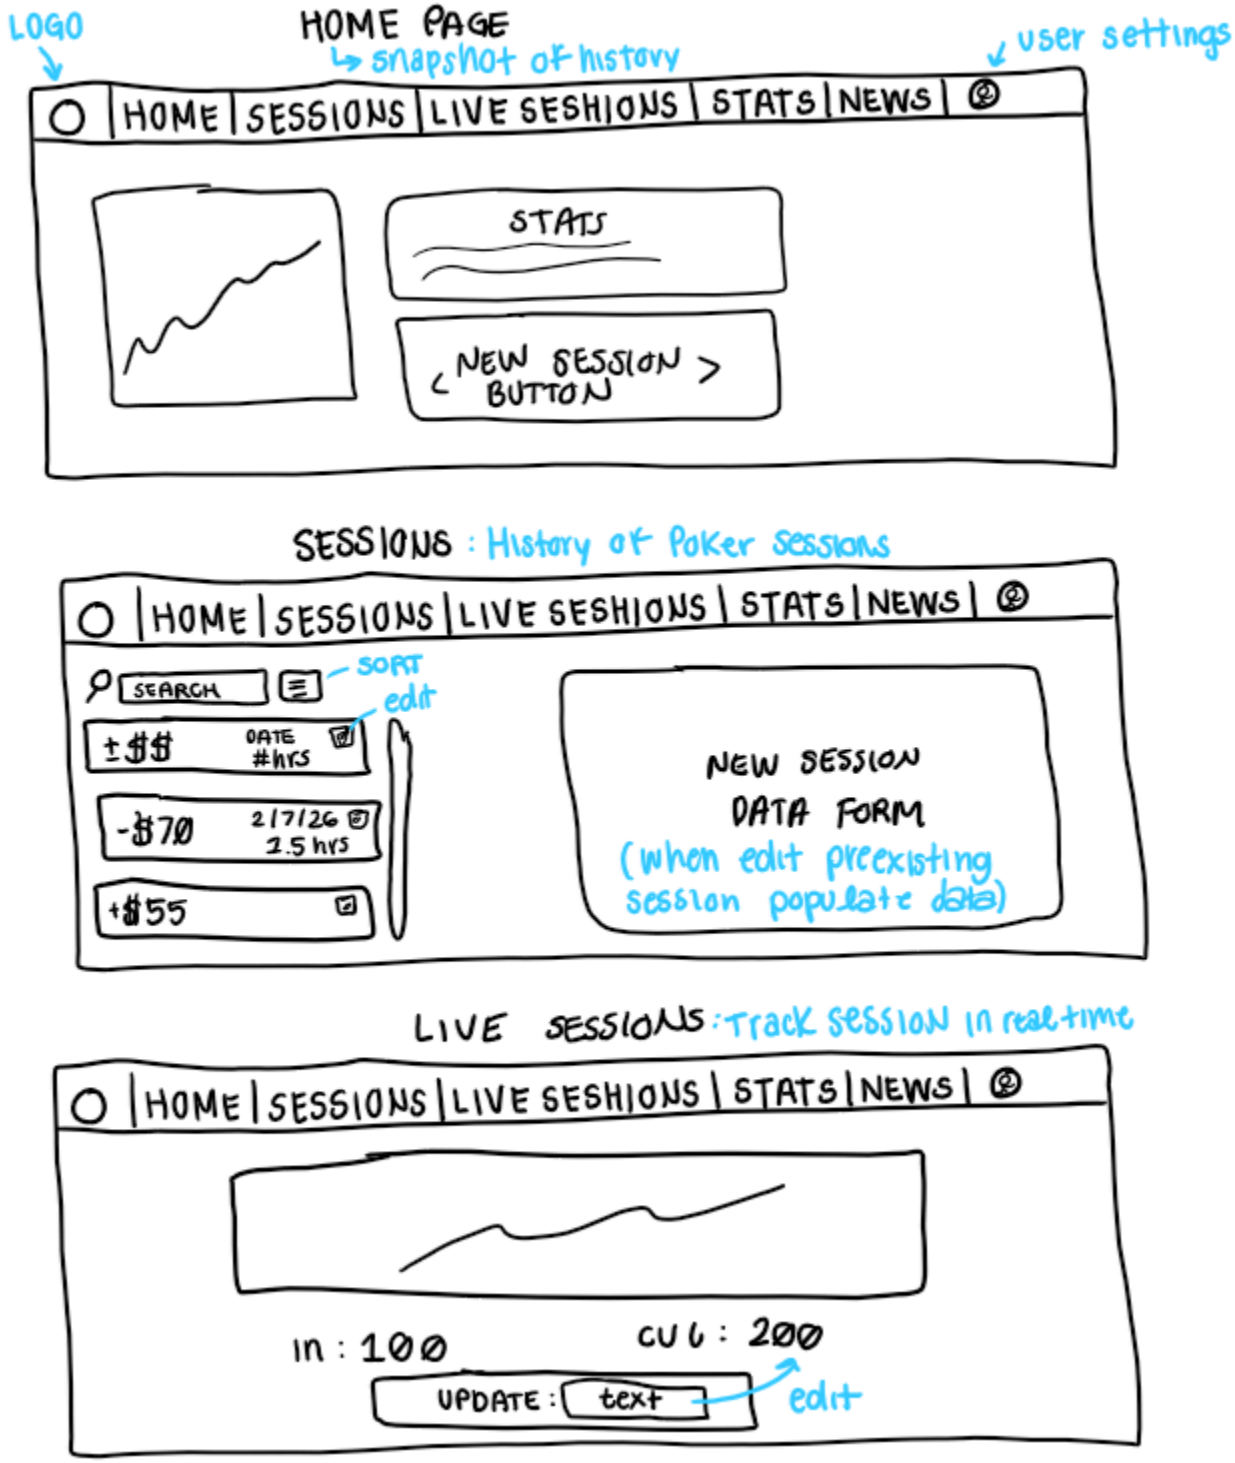
6. Audience: Our audience is serious poker players who want to track results and improve their performance over time. Chip Companion will be free and sync across devices making it more accessible than any similar service on the market.

7. Vision Statement:
    a. **For** serious poker players **who** want to track and analyze results. **Chip Companion is a** tracking tool **that** seamlessly integrates poker results across devices. **Unlike** Pokerbankrolltracker which is only available on your phone and unlike Pokertracker4 which is a paid service, **our product** is available for free and syncs across devices.
8. Version Control: https://github.com/Medoriku/Chip-Companion
9. Development Methodology: We will use an Agile methodology. We will have scrum meetings at the beginning of our weekly meetings.
10. Communication Plan: We will use MS Teams to communicate.
    a. 4:00 PM meeting every friday: Weekly Team Meeting - Software Dev Group | Meeting-Join | Microsoft Teams
11. Meeting Plan:
    a. Meeting with TA at 4:35 on Mondays preferably in person meetings but open to virtual meetings.
    b. Team meeting from 4-4:30 on MS teams

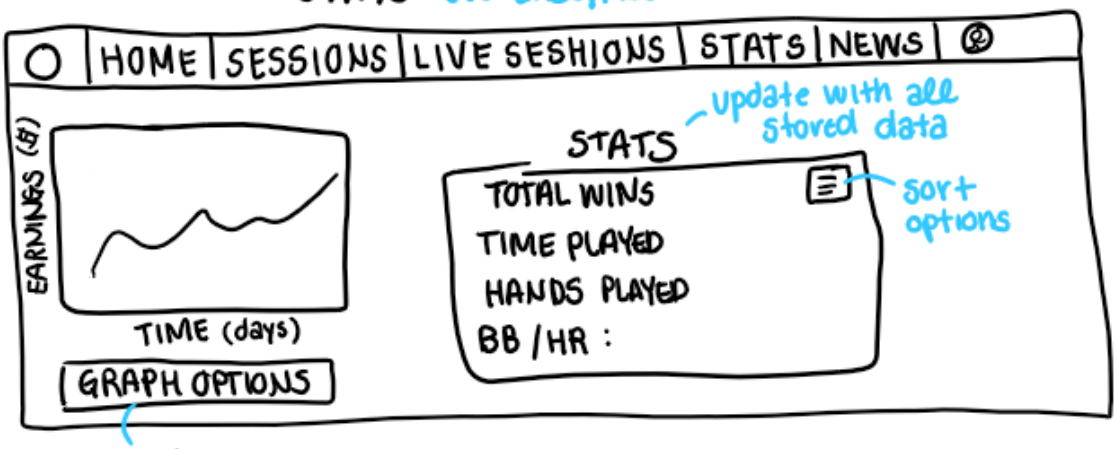
12. Use Case Diagram:



13. Wireframes:



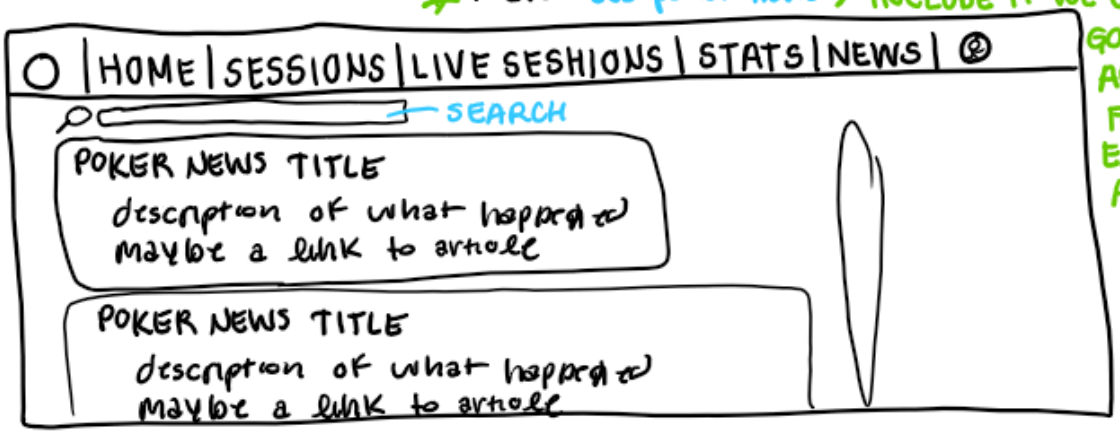
STATS: see analytics



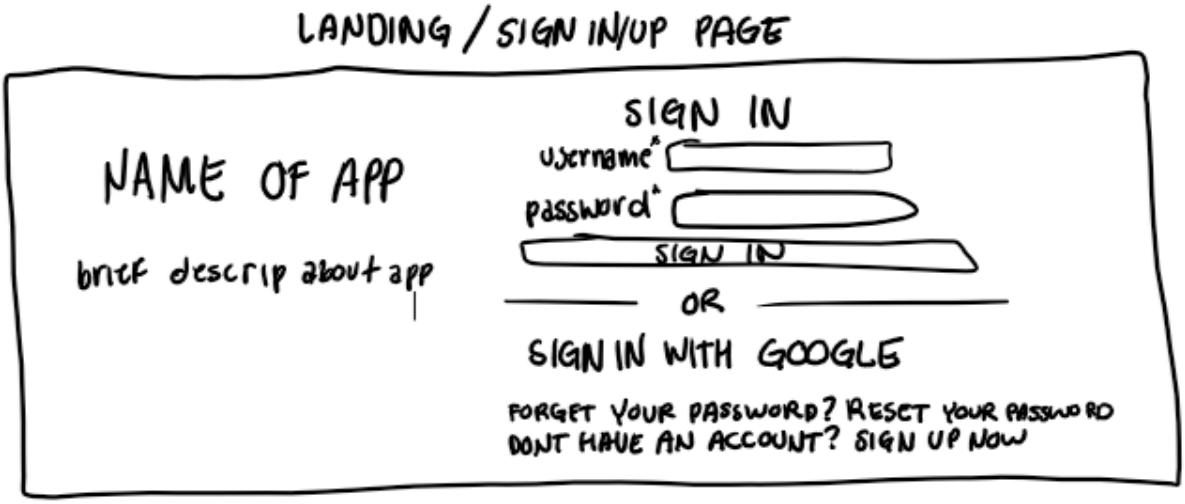
ie: edit time units to years

NEWS: see poker news

NOT CRITICAL TO INCLUDE IF WE USE GOOGLE AUTH FOR EXT API



USER SETTING: edit preferences



**EXTRA CREDIT:** Identify at least five potential risks related to your project. For each risk, describe its severity and outline suitable mitigation strategies to address it.

1. Security and Authentication
    a. Because we are dealing with player's bankrolls and betting history, a security breach could prove to be a high severity risk. Steps that we could take to mitigate this risk would be to use HTTPS, and to only store minimal personal data alongside betting history.
2. Inaccuracies leading to misleading insights
    a. If there are any errors in trend analytics or variance estimates it could lead to users making ill-informed betting decisions. This is a huge liability making it a high severity risk. Ways to mitigate this is by validating all equations and formulas against existing poker math models and by including an uncertainty/confidence interval for transparency.
3. Database Failure
    a. Because we are building an app that deals primarily with analytics, any data loss or issues with the database would render the purpose of our application obsolete. Therefore this can be considered to be a high severity risk. Steps to mitigate this could be with regular data backups, redundant databases, and manual export options.
4. Real-Time synchronization issues
    a. Since there is a real-time (live) capability in our webpage, if there is lag or delays this could be problematic. Since it is not catastrophic in magnitude, this can be considered to be a medium severity risk. Ways to mitigate it would be through real-time databases, and

synchronization progress bars (making the user's experience less frustrating).

5. User Input Errors
    a. It could be easy for users to enter incorrect information to the database which would cause errors in the app statistics. This is a low severity risk as it could be easily managed. One such way would be by implementing data constraints (Example: no negative bet values, exactly one of each card can be in play at a given time, etc.). Another mitigation strategy would be letting users go back and edit the data at any point.
